Alcohol Use Disorder and Suicide Among Veterans

**Issue**

Alcohol use disorder (AUD) is a type of substance use disorder (SUD) characterized by 11 symptoms, including drinking more or for longer than intended, drinking that interferes with activities and relationships, and an inability to moderate alcohol consumption or stop drinking entirely. Experiencing any two of these symptoms in the past year indicates the presence of AUD. AUD is a well-established risk factor for suicide, and problematic drinking is common among Veterans. Among a nationally representative sample of Veterans, 42.2% meet the criteria for a diagnosis of lifetime AUD (i.e., having had AUD at some point during their lives), while more than 14.8% meet the criteria for a diagnosis of past-year probable AUD. Veterans with lifetime AUD have higher rates of suicide attempts and suicidal ideation than Veterans without lifetime AUD do.

**Key Findings**

- Compared with male Veterans characterized as moderate drinkers, male Veterans with lifetime AUD — both those who reported current hazardous drinking and those who abstained from drinking — had increased odds of screening positive for symptoms of posttraumatic stress disorder (PTSD), depression, and suicidal thoughts and past suicide attempts. Among female Veterans, those who were currently drinking at hazardous levels, but not those who abstained from drinking, had higher risk for suicidality than did female Veterans who were moderate drinkers.

- Nonroutine discharge from military service for misconduct or disqualification was significantly associated with elevated risk for AUD, as well as with risk for suicidal ideation and behaviors.

**AUD and PTSD**

- Compared with Veterans who screen positive for probable PTSD alone, Veterans who screen positive for both probable AUD and probable PTSD may be at an increased risk for suicide and were three times as likely to have a history of suicide attempts. Veterans who screened positive for both AUD and PTSD were also more likely to screen positive for major depression, generalized anxiety disorder, suicidal ideation, and a past suicide attempt than were Veterans who screened positive for AUD alone.

- Veterans with a diagnosis of PTSD, or PTSD and AUD together, had lower scores for social connectedness and protective psychosocial characteristics than did Veterans diagnosed with AUD alone. Protective psychosocial factors were found to partially mediate the relationship between diagnostic status and risk for lifetime suicide attempts.

**AUD and Suicide Risk Among Female Veterans**

- While a current diagnosis of AUD is associated with an elevated risk for suicide among male and female Veterans, the magnitude of the effect of AUD on suicide risk is higher for female Veterans. However, the difference in magnitude was reduced after adjusting for factors such as mental health diagnoses, suggesting that this relationship might be mediated by comorbid psychiatric disorders.

- Similarly, while screening positive for military sexual trauma (MST) is associated with higher rates of AUD and other SUDs among both male and female Veterans, the increase is proportionally greater for female Veterans.

- The interaction between PTSD and a diagnosis of AUD is a stronger predictor of nonfatal intentional self-harm for Veterans Health Administration (VHA) female patients than for VHA male patients.
Alcohol Use Disorder and Suicide Among Veterans

Implications

Among Veterans, AUD is associated with an increased risk for suicidal thoughts and behaviors, as well as for other mental health concerns. The association between AUD and suicide is more pronounced for female Veterans, as is the association between MST and AUD. Both male and female Veterans who receive a diagnosis of AUD and PTSD also appear to be at particular risk for suicide and other mental health conditions.

Ways You Can Help

- Consider the variety of available evidence-based treatments for AUD, including therapy (such as behavioral therapy, to encourage self-change, or couples and family therapy, to improve relationship factors), mutual help groups (such as 12-step programs), and medication. For more information, please refer to the relevant VA/DoD Clinical Practice Guideline, available at www.healthquality.va.gov/guidelines/MH/sud.

- Ensure that Veterans receive the guideline-recommended treatments for both substance use and PTSD in co-occurring disorders. Having an SUD should not be a barrier to receiving treatment for PTSD, nor should having PTSD be a barrier to receiving treatment for a substance use disorder. For more information on treating PTSD, please refer to the VA/DoD Clinical Practice Guideline, available at www.healthquality.va.gov/guidelines/mh/ptsd/index.asp.

- Address psychosocial problems — including those related to housing, employment, and other mental health conditions — through shared decision-making and by arranging for additional services to address these concerns.

- More information and resources can be found at www.mentalhealth.va.gov/substance-abuse.

There is no single cause of suicide. It is often the result of a complex interaction of risk and protective factors at the individual, interpersonal, community, and societal levels. To prevent Veteran suicide, we must maximize protective factors and minimize risk factors at all of these levels.
